

Designation: D7032 – 21

Standard Specification for Establishing Performance Ratings for Wood-Plastic Composite and Plastic Lumber Deck Boards, Stair Treads, Guards, and Handrails¹

This standard is issued under the fixed designation D7032; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers procedures to establish a performance rating for wood-plastic composite and plastic lumber for use as exterior deck boards, stair treads, guards, and handrails. The purpose of this specification is to establish a basis for code recognition of these products or systems in exterior applications.

NOTE 1—While wood-plastic composites contain wood or other cellulosic materials, the presence of wood or other cellulosic materials in plastic lumber is not required by this specification. Due to non-wood materials in wood-plastic composites and plastic lumber the structural, physical, fire, and other attributes may not be similar to those of wood.

NOTE 2—The products addressed in this standard are considered combustible. No fire response characteristic is required in this specification except for flame spread index as determined in accordance with Test Method E84.

1.1.1 The plastic component of wood-plastic composites and plastic lumber covered by this specification shall consist primarily of thermoplastics.

1.2 Deck boards, stair treads, guards, and handrails covered by this specification are permitted to be of any code compliant shape and thickness (solid or non-solid).

1.3 Wood-plastic composites and plastic lumber are produced in a broad range of fiber and/or resin formulations. It is recognized that the performance requirements in this specification are valid for any material or combination of materials used as deck boards, stair treads, guards, or handrails.

1.4 Details of manufacturing processes are beyond the scope of this specification.

1.5 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

¹ This specification is under the jurisdiction of ASTM Committee D07 on Wood and is the direct responsibility of Subcommittee D07.02 on Lumber and Engineered Wood Products.

Current edition approved Nov. 1, 2021. Published December 2021. Originally approved in 2004. Last previous edition approved in 2017 as D7032 – 17. DOI: 10.1520/D7032-21.

1.6 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.

1.7 Table of Contents:

	Section
Scope	1
Referenced Documents	2
Terminology	3
General Requirements	4
Sampling	4.1
Sample Size	4.2
Conditioning	4.3
Flexural Tests	4.4
Temperature and Moisture Effects	4.5
Ultraviolet (UV) Resistance Test	4.6
Freeze-Thaw Resistance Test	4.7
Biodeterioration Tests	4.8
Fire Performance Tests	4.9
Deck Board Performance Requirements	5
General	5.1
Flexural Performance Tests	5.2
Determination of the Unadjusted Allowable Load	5.3
Creep-Recovery Test	5.4
Mechanical Fastener Holding Tests	5.5
Slip Resistance Test	5.6
Guard and Handrail Performance Requirements	6
General	6.1
Guardrail System Test Requirements	6.2
One- and Two-Family Dwelling	6.2.1.1
Requirements	
Handrail Test Requirements (Concentrated Load)	6.3
Report	7
Independent Inspection	8
Manufacturing Standard	9
Precision and Bias	10
Keywords	11
Two-Span Test Method	Annex A1
Commentary	Appendix X1

1.8 This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.

3. Terminology

3.1 *Definitions*—Terminology used to describe WPCs are defined in Terminologies **D9**, **D883**, **D1554**, and **D4092**, Practice **D1972**, and Classification **D4000**.

3.2 *Definitions of Terms Specific to This Standard*:

3.2.1 *center-point load*—a flexure test where the load comes in contact with the test specimen at a location that is ½ the test span.

3.2.2 *guard*—a building component or a system of building components located at or near the open sides of elevated walking surfaces that minimizes the possibility of a fall from the walking surface to a lower level.

3.2.3 *handrail*—a rail intended for grasping by the hand for guidance or support.

3.2.4 *plastic lumber*—a manufactured product made primarily from plastic materials (filled or unfilled), typically used as a building material, which is usually rectangular in cross-section.

3.2.5 *quarter-point loading*—a flexure test where the load comes in contact with the test specimen at two locations, each of which is located at ¼ the span from the specimen load support.

3.2.5.1 *Discussion*—For example, quarter-point loading for a test specimen on a 24-in. (610-mm) span would have two equal loads contact the test specimen each located 6 in. in from the test specimen load support. The distance between the two points of load would be 12 in. (305 mm).

3.2.6 *span rating*—an index number that identifies the test span used in all structural load testing, which is the maximum center-to-center support spacing for the specified end use, and allowable design capacity, in pounds per square foot (lbf/ft² (kN/m²)), determined in accordance with this specification.

3.2.6.1 *Discussion*—For example, a deck span rating of 1¹/₁₀₀ recognizes the deck board for installation perpendicular to the floor joists spaced a maximum of 16 in. (406 mm) on center, and for supporting the load combinations required by the applicable code, which in this case cannot exceed 100 lbf/ft² (4.79 kN/m²).

⁵ Available from International Code Council (ICC), 5203 Leesburg Pike, Suite 600, Falls Church, VA 22041-3401, <http://www.intlcode.org>.

3.2.7 *third-point loading*—a flexure test where the load comes in contact with the test specimen at two locations, each of which is located at $\frac{1}{3}$ the span from the specimen load support.

3.2.7.1 *Discussion*—For example, third-point loading for a test specimen on a 24-in. (610-mm) span would have two equal loads contact the test specimen each located 8 in. in from the test specimen load support. The distance between the two points of load would also be 8 in. (205 mm).

3.2.8 *wood-plastic composite (WPC)*—a composite made primarily from wood- or cellulose-based materials and plastic(s).

4. General Requirements

4.1 *Sampling*—Samples for testing shall be representative of the population being evaluated. Sampling shall be representative of the possible variations due to changes in raw materials and process variables over time. It is essential to consider batch-to-batch and shift-to-shift variability when sampling actual production. Test specimens shall be selected from several production runs of a given item. Products shall be sampled at the manufacturing site by an accredited third party inspection agency or testing laboratory. Exceptions to sampling at the manufacturing site, such as at a warehouse or distribution center, shall be documented in the test report.

4.2 *Sample Size*—Selection of a sample size depends upon the property to be estimated, the actual variation in the property occurring in the population, and the precision with which the property is to be estimated. The principles of Practice **D2915** shall be followed. The minimum sample size shall provide estimation of mean values within 5 % in accordance with 3.4.2 of Practice **D2915**.

4.3 *Conditioning*—Prior to testing, all specimens shall be conditioned to environmental conditions appropriate for the intended end use of the product. Alternatively, test specimens shall be conditioned for a minimum of 40 h at $68^{\circ}\text{F} \pm 4^{\circ}\text{F}$ ($20^{\circ}\text{C} \pm 2^{\circ}\text{C}$) and 50 ± 5 % RH. If data show that product properties are not affected by extreme moisture conditions, such as submersion, the material shall be permitted to be tested without special conditioning. When the product is to be subjected to a water soak environment, the test specimens shall be tested within 30 min upon removal from the treatment.

4.4 *Flexural Tests*—Flexural strength and stiffness shall be determined in accordance with principles of Test Methods **D4761** or **D6109**. Alternatively, to assess compliance with performance requirements in its intended installed configuration, the deck boards shall be tested according to the two-span method defined in **Annex A1**. The test specimen cross section shall be the minimum anticipated structural size for the intended end use. The test span shall be that for which code recognition is desired. The specimens shall be loaded at a constant strain rate of 1 % per minute (± 10 %). Average time to failure for each test configuration shall be recorded (see Commentary, **X1.2**). A constant strain rate of 1 % per minute is achieved by using a constant rate of test machine crosshead motion, R , (inches/minute) computed in terms of the test span, L , and the member depth, d , by the following equation:

$$R = 0.00185 \times L^2/d \quad (1)$$

For members where the depth (vertical dimension) is varying along the member length, the depth (d) shall be taken as the gross member depth at the point of maximum moment.

NOTE 3—Eq 1 is based on the maximum extreme fiber strain at midspan of a horizontally symmetric simple span member. For a product that is symmetric about its horizontal axis, Eq 1 yields the target strain rate at both the extreme tensile and extreme compressive faces. For a product that is not symmetric about its horizontal axis, the Eq 1 strain rate is the average of the strains at these faces. See Commentary for additional information.

NOTE 4—Some wood-plastic composites and plastic lumber exhibit exceptionally large deformations prior to failure in bending. Users are cautioned to take particular care in test machine set-up to accommodate large deflections, both in terms of deflection-measuring devices and support conditions.

4.4.1 *Flexural Strength*—Modulus of rupture (MOR) or moment capacity shall be reported for each specimen. Flexural strength shall be calculated from the maximum load achieved or the load at 3 % strain, whichever occurs first.

4.4.2 *Flexural Stiffness*—Apparent modulus of elasticity (MOE) or EI shall be reported for each specimen. Flexural stiffness shall be calculated from a linear least squares fit of the stress-strain curve over the range of 10 to 40 % of ultimate stress.

4.4.3 The flexural strength and stiffness for deck board, guard, and handrail materials shall be determined in accordance with 4.4 and shall be used to establish a standard baseline performance level for comparison with future production during the required quality control audits.

4.5 Temperature and Moisture Effects:

4.5.1 *Temperature Effect*—Testing shall be conducted to verify that allowable span and load ratings are applicable at a range of temperatures expected in service. For purposes of this specification, the lower and upper temperatures shall be $-20 \pm 4^{\circ}\text{F}$ ($-29 \pm 2^{\circ}\text{C}$) and $125 \pm 4^{\circ}\text{F}$ ($52 \pm 2^{\circ}\text{C}$), respectively. Flexure tests shall be conducted to failure at the desired span. A minimum of 10 specimens shall be tested at each temperature. The flexural strength and stiffness shall be determined in accordance with 4.4 and the average change in properties between the flexural strength and stiffness of the control flexural specimens and the specimens tested at low and high temperatures shall be calculated as a percentage and reported. The average change in flexural strength and stiffness properties shall be calculated by determining the difference between the control and conditioned values and dividing that difference by the control value.

4.5.2 *Moisture Effect*—Testing shall be conducted to verify that allowable span and load ratings are applicable at moisture conditions expected in service. Flexure tests shall be conducted to failure at the desired span. A minimum of 10 specimens shall be tested at moisture conditions anticipated in service (for example, high humidity, submerged). The average maximum flexural strength and stiffness shall be determined in accordance with 4.4. The average change in properties between the control specimens and those tested at the in-service moisture condition of interest shall be calculated as a percentage and reported. The average change in flexural strength and stiffness properties shall be calculated by determining the difference
