

Designation: C393/C393M – 20

Standard Test Method for Core Shear Properties of Sandwich Constructions by Beam Flexure¹

This standard is issued under the fixed designation C393/C393M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the U.S. Department of Defense.

1. Scope

1.1 This test method covers determination of the core shear properties of flat sandwich constructions subjected to flexure in such a manner that the applied moments produce curvature of the sandwich facing planes. Permissible core material forms include those with continuous bonding surfaces (such as balsa wood and foams) as well as those with discontinuous bonding surfaces (such as honeycomb).

1.2 *Units*—The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system are not necessarily exact equivalents; therefore, to ensure conformance with the standard, each system shall be used independently of the other, and values from the two systems shall not be combined.

1.2.1 Within the text, the inch-pound units are shown in brackets.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.*

1.4 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

2. Referenced Documents

2.1 ASTM Standards:²

¹ This test method is under the jurisdiction of ASTM Committee D30 on Composite Materials and is the direct responsibility of Subcommittee D30.09 on Sandwich Construction.

Current edition approved July 1, 2020. Published August 2020. Originally approved in 1957. Last previous edition approved in 2016 as C393/C393M – 16. DOI: 10.1520/C0393_C0393M-20.

3. Terminology

3.1 *Definitions*—Terminology D3878 defines terms relating to high-modulus fibers and their composites, as well as terms relating to sandwich constructions. Terminology D883 defines terms relating to plastics. Terminology E6 defines terms relating to mechanical testing. Terminology E456 and Practice E177 define terms relating to statistics. In the event of a conflict between terms, Terminology D3878 shall have precedence over the other terminologies.

3.2 Symbols:

b = specimen width

c = core thickness

CV = coefficient of variation statistic of a sample population for a given property (in percent)

d = sandwich total thickness

$D^{F,nom}$ = effective sandwich flexural stiffness

E_f = effective facing chord modulus

ϵ = measuring strain in facing

F^u = facing ultimate strength (tensile or compressive)

F_c = core compression allowable strength

F_s = core shear allowable strength

F_s^{ult} = core shear ultimate strength

F_s^{yield} = core shear yield strength

k = core shear strength factor to ensure core failure

L = length of loading span

S = length of support span

l_{pad} = length of loading pad

n = number of specimens

P = applied force

P_{max} = maximum force carried by test specimen before failure

F_z^{flu} = ultimate flatwise tensile strength

P_{max} = maximum force carried by test specimen before failure

S_{n-1} = standard deviation statistic of a sample population for a given property

σ = facing stress or strength

t = facing thickness

x_1 = test result for an individual specimen from the sample population for a given property

x = mean or average (estimate of mean) of a sample population for a given property

4. Summary of Test Method

4.1 This test method consists of subjecting a beam of sandwich construction to a bending moment normal to the plane of the sandwich. Force versus deflection measurements are recorded.

4.2 The only acceptable failure modes are core shear or core-to-facing bond. Failure of the sandwich facing preceding failure of the core or core-to-facing bond is not an acceptable failure mode. Use Test Method [D7249/D7249M](#) to determine facing strength.

5. Significance and Use

5.1 Flexure tests on flat sandwich construction may be conducted to determine the sandwich flexural stiffness, the core shear strength and shear modulus, or the facings compressive and tensile strengths. Tests to evaluate core shear strength may also be used to evaluate core-to-facing bonds.

5.2 This test method is limited to obtaining the core shear strength or core-to-facing shear strength and the stiffness of the sandwich beam, and to obtaining load-deflection data for use in calculating sandwich beam flexural and shear stiffness using Practice [D7250/D7250M](#).

NOTE 1—Core shear strength and shear modulus are best determined in accordance with Test Method [C273](#), provided bare core material is available.

5.3 Facing strength is best determined in accordance with Test Method [D7249/D7249M](#).

5.4 Practice [D7250/D7250M](#) covers the determination of sandwich flexural and shear stiffness and core shear modulus using calculations involving measured deflections of sandwich flexure specimens.

5.5 This test method can be used to produce core shear strength and core-to-facing shear strength data for structural design allowables, material specifications, and research and development applications; it may also be used as a quality control test for bonded sandwich panels.

5.6 Factors that influence the shear strength and shall therefore be reported include the following: facing material, core material, adhesive material, methods of material fabrication, core geometry (cell size), core density, adhesive thickness, specimen geometry, specimen preparation, specimen conditioning, environment of testing, specimen alignment, loading procedure, speed of testing, and adhesive void content. Further, core-to-facing strength may be different between precured/bonded and co-cured facings in sandwich panels with the same core and facing material.

NOTE 2—Concentrated loads on beams with thin facings and low density cores can produce results that are difficult to interpret, especially close to the failure point. Wider load pads with rubber pads may assist in distributing the loads.

6. Interferences

6.1 *Material and Specimen Preparation*—Poor material fabrication practices and damage induced by improper specimen machining are known causes of high data scatter in composites and sandwich structures in general. A specific material factor that affects sandwich cores is variability in core density. Important aspects of sandwich core specimen preparation that contribute to data scatter include the existence of joints, voids or other core discontinuities, out-of-plane curvature, and surface roughness.

6.2 *Geometry*—Specific geometric factors that affect core shear strength include core orthotropy (that is, ribbon versus transverse direction for honeycomb core materials) and core cell geometry.

6.3 *Environment*—Results are affected by the environmental conditions under which specimens are conditioned, as well as the conditions under which the tests are conducted. Specimens tested in various environments can exhibit significant differences in both strength behavior and failure mode. Critical environments must be assessed independently for each specific combination of core material, facing material, and core-to-facing interfacial adhesive (if used) that is tested.

6.4 *Core Material*—If the core material has insufficient shear or compressive strength, it is possible that the core may locally crush at or near the loading points, thereby resulting in facing failure due to local stresses. In other cases, facing failure can cause local core crushing. When there is both facing and core failure in the vicinity of one of the loading points, it can be difficult to determine the failure sequence in a post-mortem inspection of the specimen as the failed specimens look very similar for both sequences. For some core materials, the shear strength is a function of the direction that the core is oriented relative to the length of the specimen.

7. Apparatus

7.1 *Micrometers and Calipers*—A micrometer with a 4 to 7 mm [0.16 to 0.28 in.] nominal diameter ball-interface or a flat

anvil interface shall be used to measure the specimen thickness. A ball interface is recommended for thickness measurements when facings are bonded to the core and at least one surface is irregular (for example, the bag-side of a thin facing laminate that is neither smooth nor flat). A micrometer or caliper with a flat anvil interface is recommended for thickness measurements when facings are bonded to the core and both surfaces are smooth (for example, tooled surfaces). A micrometer or caliper with a flat anvil interface shall be used for measuring length and width, as well as the specimen thickness when no facings are present. The use of alternative measurement devices is permitted if specified (or agreed to) by the test requestor and reported by the testing laboratory. The accuracy of the instruments shall be suitable for reading to within 1 % of the sample dimensions. For typical specimen geometries, an instrument with an accuracy of ± 0.025 mm [± 0.001 in.] is adequate for the length, width, and thickness measurements.

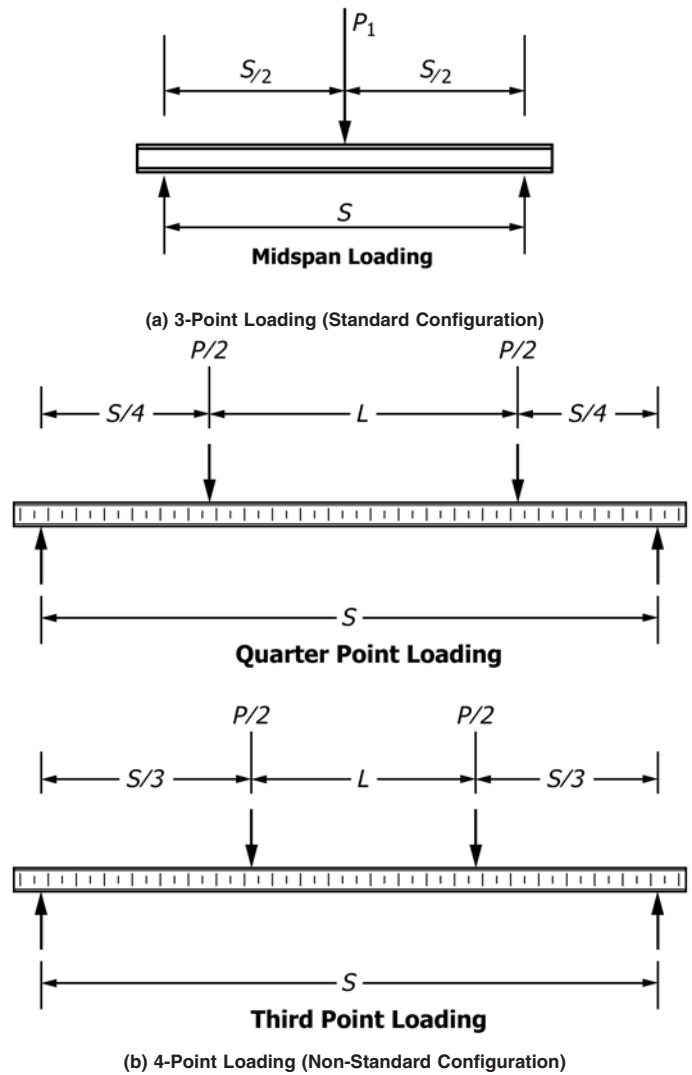

NOTE 3—The accuracies given above are based on achieving measurements that are within 1 % of the sample length, width, and thickness.

7.2 Loading Fixtures—The loading fixture shall consist of either a 3-point or 4-point loading configuration with two support bars that span the specimen width located below the specimen, and one or two loading bars that span the specimen width located on the top of the specimen (Fig. 1). The force shall be applied vertically through the loading bar(s), with the support bars fixed in place in the test machine.

7.2.1 Standard Configuration—The standard loading fixture shall be a 3-point configuration and shall have the centerlines of the support bars separated by a distance of 150 mm [6.0 in.].

7.2.2 Non-Standard Configurations—All other loading fixture configurations are considered non-standard, and details of the fixture geometry shall be documented in the test report. Fig. 3 shows a typical 4-point short beam test fixture. Non-standard 3- and 4-point loading configurations have been retained within this standard (a) for historical continuity with previous versions of Test Method C393, (b) because some sandwich panel designs require the use of non-standard loading configurations to achieve core or bond failure modes, and (c) load-deflection data from non-standard configurations may be used with Practice D7250/D7250M to obtain sandwich beam flexural and shear stiffnesses.

7.2.3 Support and Loading Bars—The bars shall be designed to allow free rotation of the specimen at the loading and support points. The bars shall have sufficient stiffness to avoid significant deflection of the bars under load; any obvious bowing of the bars or any gaps occurring between the bars and the test specimen during loading shall be considered significant deflection. The recommended configuration has a 25 mm [1.0 in.] wide flat steel loading block to contact the specimen (through rubber pressure pads) and is loaded via either a cylindrical pivot or a V-shaped bar riding in a V-groove in the top of the flat-bottomed steel loading pad. The tips of the V-shaped loading bars shall have a minimum radius of 3 mm [0.12 in.]. The V-groove in the loading pad shall have a radius larger than the loading bar tip and the angular opening of the groove shall be such that the sides of the loading bars do not contact the sides of the V-groove during the test. Loading bars consisting of 25 mm [1.0 in.] diameter steel cylinders may also

	Configuration	Support Span (S)	Load Span (L)
Standard	3-Point (Mid-Span)	150 mm [6.0 in.]	0.0
Non-Standard	4-Point (Quarter-Span)	S	S/2
	4-Point (Third-Span)	S	S/3

FIG. 1 Loading Configurations

be used, but there is a greater risk of local specimen crushing with cylindrical bars. Also, the load and support span lengths tend to increase as the specimen deflects when cylindrical loading bars without V-grooved loading pads are used (for example, rolling supports).

7.2.4 Pressure Pads—Rubber pressure pads having a Shore A durometer of approximately 60, a nominal width of 25 mm [1.0 in.], a nominal thickness of 3 mm [0.125 in.], and spanning the full width of the specimen shall be used between the loading bars and specimen to prevent local damage to the facings.

7.3 Testing Machine—The testing machine shall be in accordance with Practices E4 and shall satisfy the following requirements:
