

Standard Test Method for Laboratory Measurement of Impact Sound Transmission Through Floor-Ceiling Assemblies Using the Tapping Machine¹

This standard is issued under the fixed designation E 492; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

This test method is one of several for evaluating the sound insulating properties of building elements. It is designed to measure the impact sound transmission performance of an isolated floor-ceiling assembly, in a controlled laboratory environment. Others in the set deal with field measurement of impact sound transmission through floor-ceiling assemblies (Test Method E 1007), measurement of sound isolation in buildings (Test Method E 336), the measurement of sound transmission through a common plenum between two rooms (Test Method E 1414), and the laboratory measurement of airborne sound transmission loss of building partitions such as walls, floor-ceiling assemblies, doors, and other space-dividing elements (Test Method E 90).

1. Scope

1.1 This test method covers the laboratory measurement of impact sound transmission of floor-ceiling assemblies using a standardized tapping machine. It is assumed that the test specimen constitutes the primary sound transmission path into a receiving room located directly below and that a good approximation to a diffuse sound field exists in this room.

1.2 Measurements may be conducted on floor-ceiling assemblies of all kinds, including those with floating-floor or suspended ceiling elements, or both, and floor-ceiling assemblies surfaced with any type of floor-surfacing or floor-covering materials.

1.3 This test method prescribes a uniform procedure for reporting laboratory test data, that is, the normalized one-third octave band sound pressure levels transmitted by the floor-ceiling assembly due to the tapping machine.

1.4 *Laboratory Accreditation*—The requirements for accrediting a laboratory for performing this test method are given in Annex A2.

1.5 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.6 *This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and*

health practices and determine the applicability of regulatory limitations prior to use.

3. Terminology

3.1 The following terms used in this test method have specific meanings that are defined in Terminology **C 634**:

airborne sound
average sound pressure level
background noise
decay rate
decibel
diffuse sound field
impact insulation class
one-third octave band
receiving room
reverberant sound field
reverberation room
sound absorption
sound pressure level

3.2 *Definitions of Terms Specific to This Standard*:

3.2.1 *receiving room*—a reverberation room below the floor specimen under test in which the sound pressure levels due to the tapping machine are measured.

4. Summary of Test Method

4.1 A standard tapping machine is placed in operation on a floor specimen that is intended to represent a horizontal separation between two rooms, one directly above the other. The average spectrum of the sound pressure levels produced by the tapping machine is measured in the receiving room below in one-third octave bands.

4.2 Since the spectrum depends on the absorption of the receiving room, the sound pressure levels are normalized to a reference absorption for purposes of comparing results obtained in different receiving rooms that differ in absorption.

5. Significance and Use

5.1 The spectrum of the noise in the room below the test specimen is determined by the following:

5.1.1 The size and the mechanical properties of the floor-ceiling assembly, such as its construction, surface, mounting or edge restraints, stiffness, or internal damping,

5.1.2 The acoustical response of the room below,

5.1.3 The placement of the object or device producing the impacts, and

5.1.4 The nature of the actual impact itself.

5.2 This test method is based on the use of a standardized tapping machine of the type specified in **8.1** placed in specific positions on the floor. This machine produces a continuous series of uniform impacts at a uniform rate on a test floor and generates in the receiving room broadband sound pressure levels that are sufficiently high to make measurements possible beneath most floor types even in the presence of background noise. The tapping machine itself, however, is not designed to simulate any one type of impact, such as produced by male or female footsteps.

5.3 Because of its portable design, the tapping machine does not simulate the weight of a human walker. Therefore, the structural sounds, i.e., creaks or booms of a floor assembly caused by such footstep excitation is not reflected in the single number impact rating derived from test results obtained by this test method. The degree of correlation between the results of tapping machine tests in the laboratory and the subjective acceptance of floors under typical conditions of domestic impact excitation is uncertain. The correlation will depend on both the type of floor construction and the nature of the impact excitation in the building.

5.4 In laboratories designed to satisfy the requirements of this test method, the intent is that only significant path for sound transmission between the rooms is through the test specimen. This is not generally the case in buildings where there are often many other paths for sounds—*flanking sound transmission*. Consequently sound ratings obtained using this test method do not relate directly to sound isolation in buildings; they represent an upper limit to what would be measured in a field test.

5.5 This test method is not intended for field tests. Field tests are performed according to Test Method **E 1007**.

6. Test Rooms

6.1 The test facility shall be so constructed and arranged that the test specimen constitutes the only important transmission path for the tapping machine sound.

NOTE 1—Common methods for ensuring that this requirement is satisfied include mounting the specimen resiliently in the test opening, mounting the specimen in a resiliently supported test frame, and supporting rooms resiliently. In general, all rigid connections between the specimen and the test rooms should be avoided.

6.2 The spatial variations of sound pressure level measured in the receiving room shall be such that the precision requirements in **Annex A1** are satisfied at all frequencies.

6.3 *Volume of Receiving Room*—The recommended minimum volume of the receiving room is 125 m³.

NOTE 2—See Test Method **E 90** for recommendations for new construction.

6.4 *Room Absorption*—The sound absorption in the receiving room should be low to achieve the best possible *simulation*

⁴ Available from International Electrotechnical Commission (IEC), 3 rue de Varembé, Case postale 131, CH-1211, Geneva 20, Switzerland, <http://www.iec.ch>.

of the ideal diffuse field condition, and to minimize the region dominated by the direct field of the test specimen. In the frequency range that extends from $f = 2000/V^{1/3}$ to 2000 Hz, the absorption in the receiving room (as furnished with diffusers) should be no greater than:

$$A = V^{2/3}/3 \quad (1)$$

where:

V = the room volume, m^3 , and

A = the sound absorption of the room, m^2 .

6.4.1 For frequencies below $f = 2000/V^{1/3}$, somewhat higher absorption may be desirable to accommodate requirements of other test methods (for example, **ISO 3741**); in any case, the absorption should be no greater than three times the value given by Eq 1.

NOTE 3—For frequencies above 2000 Hz, atmospheric absorption may make it impossible to avoid a slightly higher value than that given in Eq 1.

6.5 During the sound pressure level and sound absorption measurements in the receiving room the average temperature shall be in the range $22 \pm 5^\circ\text{C}$ and the average relative humidity shall be at least 30 %.

6.6 During the sound pressure level and the corresponding sound absorption measurements, variations in temperature and humidity in the receiving room shall not exceed 3°C and 3 % relative humidity respectively. Temperature and humidity shall be measured and recorded as often as necessary to ensure compliance.

6.6.1 If a relative humidity of at least 30 % can not be maintained in the receiving room, users of the test method shall verify by calculation that changes in the $10 \log A_1$ term (see 12.4) due to changes in temperature and humidity do not exceed 0.5 dB.

NOTE 4—Procedures for calculating air absorption are described in Test Method **C 423**.

7. Test Specimens

7.1 The test specimen shall be prepared and described in the test report in accordance with Annex A1 of Test Method **E 90**.

7.2 *Size and Mounting*—The test specimen shall have a minimum lateral dimension of 2.4 m. An area of at least 10 m^2 is recommended. The test specimen shall include all of the essential constructional elements and surfacing materials normally found in an actual installation. Some elements may have to be reduced in size to fit each laboratory's test opening. The test specimen shall be sealed to prevent tapping machine operational sounds from entering the room below. The specimen shall be structurally isolated from the receiving room to avoid significant transmission of vibration from the specimen through the supporting structure to the room below.

7.3 Floor-surfacing materials, such as vinyl, carpets and pads, especially when installed with adhesive, significantly affect the response of the test specimen to impacts, both during test and in normal use. Consequently, such materials shall be deemed parts of the test specimen. The materials and the manner of installing them shall be fully described in the test report. The floor-surfacing material shall cover the whole test specimen, not merely the portion under the impact machine.

8. Tapping Machine

8.1 This test method is based on the use of a standardized tapping machine that conforms to the following specifications:

8.1.1 The tapping machine shall be motor-driven.

8.1.2 The tapping machine shall have five hammers equally spaced in a line. The distance between centerlines of neighboring hammers shall be $100 \pm 3 \text{ mm}$.

8.1.3 Each hammer shall have an effective mass of $500 \pm 6 \text{ g}$ and shall fall freely from a height of $40 \pm 3 \text{ mm}$.

8.1.4 The falling direction of the hammers shall be perpendicular to the test surface to within $\pm 0.5^\circ$.

8.1.5 The part of the hammer carrying the impact surface shall be cylindrical with a diameter of $30 \pm 0.2 \text{ mm}$.

8.1.6 The impact surface shall be of hardened steel and shall be approximately spherical with a curvature radius of $500 \pm 100 \text{ mm}$.

NOTE 5—The mean curvature radius for each hammer face may be determined using a spherometer or other means.

8.1.7 The time between successive impacts shall be $100 \pm 20 \text{ ms}$.

8.1.8 Since friction in the hammer guidance system can reduce the velocity of the hammer at impact, the tapping machine shall be checked for friction between the hammers and the guidance system. Any friction found should be eliminated or reduced as much as possible.

8.1.9 Following adjustment of the hammer drop in accordance with the specifications, the tapping machine is ready for use on any floor structure, including those surfaced with soft or resilient materials.

NOTE 6—The above requirements are a subset of the ISO 140/6 requirements.

8.2 *Tapping Machine Positions*—The tapping machine positions and orientations described in the following must be used. **Fig. 1** illustrates one case.

8.2.1 *Position 1*—The middle hammer of the tapping machine shall be coincident with the midpoint of the floor area, that is, the point of intersection of floor diagonals. In framed construction, adjust this point to the centerline of the closest structural member or other support member, and arrange the tapping machine so that all hammers fall on the joist.

8.2.2 *Position 2*—Same as position 1, except rotate the tapping machine 90° about the axis of the middle hammer.

8.2.3 *Position 3*—Displace the tapping machine laterally from position 1, such that the long dimension of the machine is centered midway between and parallel to the central structural member. In the case of homogeneous concrete slab floors or solid deck construction without joists, the lateral displacement of the tapping machine shall be 0.6 m from that of position 1.

8.2.4 *Position 4*—Position the tapping machine so that all hammers fall on a 45° radial line extending from the middle hammer point of position 1. Locate the middle hammer 0.6 m from the midpoint of position 1.

9. Instrumentation Requirements

9.1 The measurement process must account for level fluctuations caused by spatial and temporal variations. Various systems of data collection and processing are possible, ranging
